

RMD ENSO Report:

26 August 2025

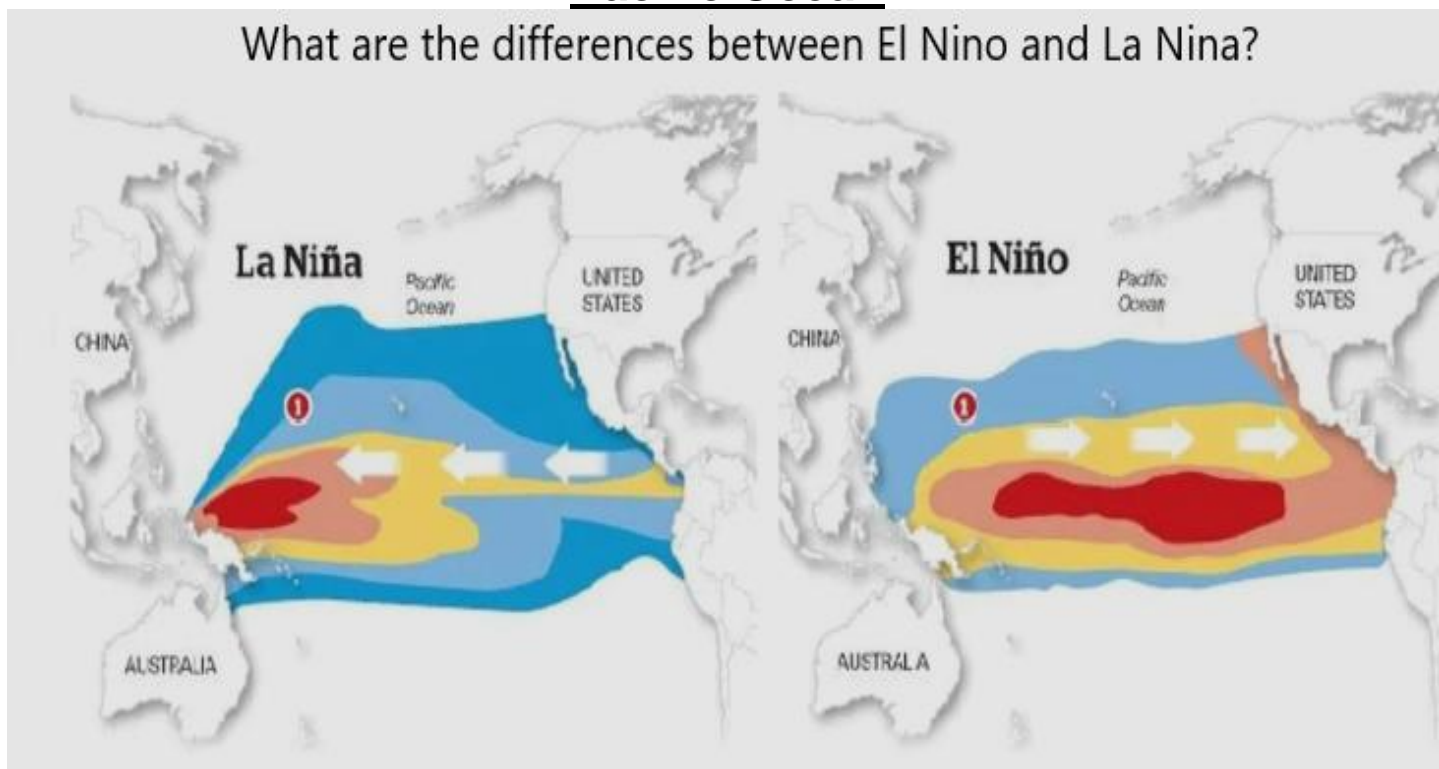

Compiled by Dirk J Fourie

This is not presented as a commodity trading recommendation. Weather is only one of many factors which can influence the market on any given day.

A negative Indian Ocean Dipole event increasingly likely over spring

*The Pacific Ocean is monitored closely for the current state of the **El Niño–Southern Oscillation (ENSO)**. ENSO refers to the oscillation between warmer (El Niño) and cooler (La Niña) states of the central and eastern tropical Pacific region. ENSO is considered one of the dominant modes of climate variability in Australia. The influence of each individual event varies, particularly in conjunction with other climate indicators such as the Indian Ocean Dipole (IOD). The ENSO signal is characterised by sea surface temperature (SST) patterns in the central and eastern tropical Pacific. Cooler than average SSTs are associated with La Niña, while warmer SSTs are associated with El Niño.*

Pacific Ocean

El Niño /La Niña map

- The El Niño–Southern Oscillation (ENSO) remains neutral. The latest Niño3.4 value for the week ending 24 August is -0.28°C . Neutral ENSO values for Niño3.4 are between -0.8°C and $+0.8^{\circ}\text{C}$. While sub-surface waters in the tropical Pacific have shown signs of cooling in recent weeks, atmospheric indicators remain mostly neutral.
- The Bureau's model predicts a neutral ENSO (neither El Niño nor La Niña) until at least January. This is consistent with most international models assessed, although some indicate the potential for borderline La Niña levels. There is a relatively large spread in the model forecasts, indicating more uncertainty than usual in the ENSO forecast.

Indian Ocean

The Indian Ocean Dipole (IOD) is defined by the difference in sea surface temperatures between the eastern and western tropical Indian Ocean. The influence of the IOD varies in conjunction with other climate indicators such as the El Niño–Southern Oscillation (ENSO).

During a negative IOD, waters are typically warmer than average in the eastern parts of the tropical Indian Ocean and cooler than average in the west. During a positive event, the reverse occurs, with cooler than average waters in the eastern parts of the tropical Indian Ocean and warmer in the west. Specific regions are monitored in the eastern and western Indian Ocean to identify IOD event development.

INDIAN OCEAN DIPOLE

Neutral phase

The Indian Ocean Dipole.

- The Indian Ocean Dipole (IOD) is neutral; however, the last 5 weeks of the IOD index have been below the negative IOD threshold. The latest IOD index value for the week ending 24 August is -1.20°C . Sustained index values less than or equal to -0.4°C for at least 8 weeks are typical of a negative IOD event.
- It is likely that the Indian Ocean Dipole is in the early stages of a negative IOD phase, with further development likely. The Bureau's model predicts a negative phase of the IOD during spring, with a return to neutral in early summer. This is consistent with all international models assessed and the typical IOD life cycle.

INDIAN OCEAN DIPOLE

Positive phase

INDIAN OCEAN DIPOLE

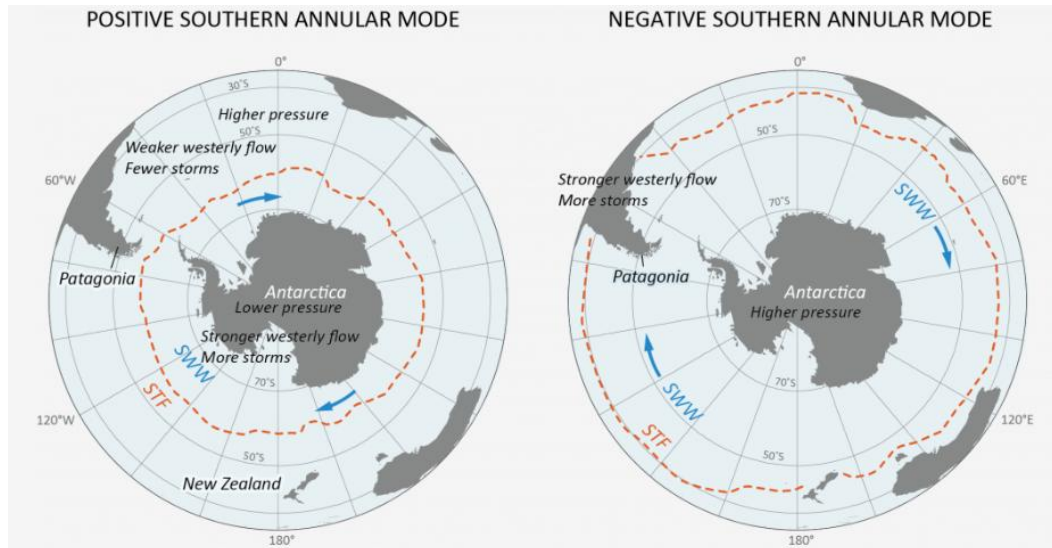

Negative phase

Southern Annular Mode (SAM)

The Southern Annular Mode (SAM) refers to the north-south movement of rain-bearing westerly winds and weather systems in the Southern Ocean, compared to the usual seasonal position. A positive SAM refers to a southward shift while a negative SAM refers to a northward shift. The typical impact on Australian rainfall from positive and negative phases of SAM depends on the time of year and interaction with other climate indicators such as El Niño or La Niña.

Sustained values of the SAM index above +1 indicate a positive SAM event, while sustained values below -1 indicate a negative SAM event

The Southern Annular Mode (SAM) remains neutral. The latest Niño3.4 value for the week ending 24 August is -0.28°C . Neutral ENSO values for Niño3.4 are between -0.8°C and $+0.8^{\circ}\text{C}$. While sub-surface waters in the tropical Pacific have shown signs of cooling in recent weeks, atmospheric indicators remain mostly neutral.

- Since July 2024, sea surface temperatures (SSTs) in the Australian region have been the warmest or second warmest on record for each respective month. Similarly, global SSTs remain substantially above average, with July 2025 the third warmest on record.
- The sea surface temperatures (SST) analysis for the week ending 24 August 2025 shows warmer than average waters across much of the Australian region, despite some cooling in recent weeks in the Coral Sea and parts of the north. Cooler than average waters have emerged in the Gulf of Carpentaria in the last fortnight.
- Forecasts for September to November show warmer-than-average SSTs to the north, east, and south-east of Australia, with near-average temperatures around south-west Western Australia and South Australia.
